

# Miscellaneous Notes on Statistical Mechanics

kdeoskar@berkeley.edu

This is a collection of random facts, theorems, exercises, and illustrations I've come across/thought up while learning Statistical Mechanics. Topics may be organized in a slightly nonsensical manner (sorry). Any errors are due to my own ignorance - please feel free to reach out and correct me!

This template is based heavily off of the one produced by [Kevin Zhou](#).

## 1 What is Entropy?

Coloquially, Entropy is often described as the disorder associated with a system, but perhaps a slightly more specific description would be that:

Entropy tells us how the energy of a system can be distributed amongst the various states the system can take.

### 1.1 Thermodynamics Motivation

A statement [\[1\]](#)

## 2 What the hell is a Thermodynamic Potential?

### 2.1 In 100 words

Internal Energy  $U$  is cool, and

$$dU = T \cdot dS - P \cdot dV + \mu \cdot dN$$

i.e. changes in  $S, P, N$  cause change in  $U$  with proportionality constant given by  $T, -P, \mu$ . So,  $S, P, N$  are called the **Natural Variables of  $U$** .

Thermodynamic Potentials like Enthalpy, Gibbs Energy, Free Energy are analogous to  $U$  but have some other set of natural variables other than  $S, P, N$ . They capture the essence of the "Energy" we're interested in keeping track of in different situations.

For example,  $U$  is constant for constant  $S, P, N$ . But entropy is difficult to experimentally measure and so to study chemical reactions we'd like to have a version of  $U$  which has natural variables  $P, V, N$  instead. We build this new version of  $U$  by carrying out a **Legendre Transform**, and it is called **Enthalpy**. We obtain the Gibbs Energy and Free energy via other Legendre transforms.

### 2.2 In more detail...

Internal energy is defined via an equation/function of state i.e.  $U = U(\text{state variables})$ . In particular, this means that if we move from one equilibrium state to another, the change in internal energy is the same irrespective of *how* we moved between the two equilibrium states in parameter space (**Fact check this.**)

But it's not unique. Taking  $U$  and adding to it some other combination of functions of state like  $p, V, T$  etc. gives us back another function of state. Eg.  $U + pV$ ,  $U - TS$ , etc. (Of course, whatever we add has to also have units of energy)

Most of these functions of state aren't super useful, but there are a few which are of interest. These are called **Thermodynamic potentials**. The reason for this name is because they play a similar role to potentials in classical mechanics, wherein there is an associated (generalized) force "induced" by the potential.

The different Thermodynamic Potentials have different **natural variables** i.e. variables which cause changes in the potential (and thus to which there are associated forces), and we go between different Thermodynamic Potentials by a procedure which changes the natural variables - namely, we apply **Legendre Transformations**.

### 2.3 Conjugate Variables

As discussed earlier **(Add discussion, if not already there)**, the first law of thermodynamics states that for internal energy  $U$ ,  $dU$  is of the form

$$dU = \sum_i p_i dq^i$$

where  $(q^i, p_i)$  are **conjugate variables**, with  $p_i$  being intensive and  $q^i$  being extensive. A pair  $(q^i, p_i)$  of this type which contributes to the internal energy are called **conjugate variables**. For example,  $\{-p, V\}$  for an Ideal Gas, or  $\{\mathbf{B}, \mathbf{M}\}$  for a Magnet [3]. This is slightly different from the notion of conjugate variables in Classical Mechanics because the underlying mathematical structure for Thermodynamics is **contact geometry** whereas it is **symplectic geometry** for Classical Mechanics [6] [4] [5]. **(Add more content to this section)**

### 2.4 Legendre Transformations

### 2.5 Intuition for Gibbs Free Energy

[2]

### **3 The Definition of Temperature**

#### **3.1 Temperature outside of equilibrium?**

[7]
