Recap

Some important results we've built in the last few lectures are:

- Rank Theorem (enter the statement here later). Last time, we applied this to $k-$slices. We argued that if we have $\S^k \hookrightarrow M^m$ and if locally S^k is a $k-$slice [finish later]
- Then, we spoke about Level Sets. Recall that if we have a smooth map $F : M^m \to N^n$, the inverse image of a point $q \in N$ i.e. $F^{-1}(q) \subseteq M$ is an embedded submanifold, given that it satisfies certain properties.

1.1 Constant Rank Level Set Theorem:

Theorem: If $F : M^m \to N^n$ is smooth and of constant rank r, then for any $q \in N$, the level set $F^{-1}(q) \subset M$ is a proper submanifold of M with dimension $(m - r)$.

Proof: We want to employ the rank theorem.

Let $S = F^{-1}(q)$. Applying the rank theorem, we obtain charts (U, ψ) on M and (V, ψ) on N such that $\psi \circ F \circ \phi^{-1}$ has the coordinate representation

$$(x^1, \ldots, x^r, x^{r+1}, \ldots, x^m) \mapsto (x^1, \ldots, x^r, 0, dots, 0)$$

So, if $\psi(q) = (c^1, \ldots, c^r, 0, \ldots 0)$, then the preimage in local coordinates on M has the form $\{(c^1, \ldots, c^r, x^{r+1}, x^m) : x^{r+1}, x^m \in \mathbb{R}\} \cap \phi(U)$ such that

But this is just a $k-$slice. So, around each point, we have a local k-slice. And we saw last time that a l ocal k-slice is an embedded submanifold of M. Further, $F^{-1}(q)$ is closed in M so it is a proper embedding.

Corollary: If $F : M \to N$ is a submersion, then $F^{-1}(q)$ is an $(m-n)$-dimensional submanifold.

Regular Level sets

Given a smooth map $F : M^m \to N^n$

- a point $p \in M$ is ***regular*** if dF_p is surjective at that point.
- Otherwse, the point p is called a ***critical point***.
- A point $q \in N$ is a ***regular value*** if all points in $F^{-1}(q)$ are regular.
- Otherwise, q is called a ***critical value***.

Example: For a smooth function $F : R \to R$, $x \in \mathbb{R}$ is a critcal point if and only if $f'(x) = 0$.

[Insert Image]

Just visually speaking, it looks like there are much fewer critical values than critical points. We'll say more about this in the next chapter when we deal with *Sard's Theorem*.

Remark:

Theorem (Regular Level Set THeorem:) If $F : M^m \to N^n$ is a smooth map between manifolds and $q \in N$ is a regular value, then its inverse image $F^{-1}(q) \subseteq M$ is a smooth $(m-n)-$dimensional submanifold of M.

Proof: Let $U = \{p \in M \ : \ rank(dF_p) = dimN\} \subseteq M$. i.e. the set of points where F has full rank. This is an open subset of M because if $q \in N$ is a regular value then $F^{-1}(q) \subseteq U$.

Then $F\big|_U$ is a submersion and by the Constant Rank Theorem for Level Sets, $F^{-1}(q) \hookrightarrow U$ is a smooth embedding of an $(m-n)$ dimensional submanifold.

Finally, $U \hookrightarrow M$ is also a smooth embeddnig, so the composition $F\big|_U \hookrightarrow U \hookrightarrow M$ is also a smooth embedding.
[Re-write the above].

Examples:

- Consider $F : \mathbb{R}^2 \to \mathbb{R}^2$ defined as
$$(x, y) \mapsto x^2 - y^2$$
Then,
$$dF_{(x,y)} = \begin{bmatrix} 2x & -2y \end{bmatrix}$$
which has rank 1 unless $x = y = 0$. i.e. the set of regular values if $\mathbb{R}^2 \setminus \{0\} \subseteq_{open} \mathbb{R}^2$.
So, $F^{-1}(c)$ is an embedded $(2-1) = 1$ dimensional submanifold of $\mathbb{R}^2$.

- $\mathbb{S}^n \subseteq \mathbb{R}^{n+1}$ can be thought of as a level set of
$$F : \mathbb{R}^{n+1} \to \mathbb{R}^1, \quad (x^1, \ldots, x^{n+1}) \mapsto (x^1)^2 + \cdots + (x^{n+1})^2$$
So, $\mathbb{S}^n = F^{-1}(1)$. If we can check that $1 \in \mathbb{R}$ is a regular value of F then our results above tell us that $\mathbb{S}^n = F^{-1}(1)$ is an embedded submanifold of $\mathbb{R}^2$.

  To do so, we calculate the differential of F and make sure it is of constant rank at any pre-image of 1.

  The differential of F is
$$df_{(x,y)} = \begin{bmatrix} 2x^1 & \cdots & 2x^{n+1} \end{bmatrix}$$
and this map has constant rank except at $(0, \ldots, 0) \notin \mathbb{S}^n$. Thus, the Regular Level Set Theorem (RLST) tells us that
$$\mathbb{S}^n \subseteq \mathbb{R}^{n+1}$$
is an $(n+1-1) = n$ dimensional submanifold.

- (Converse not necessarily true) Consider the function $F : \mathbb{R}^2 \to \mathbb{R}$ which acts as
$$(x, y) \mapsto \left((x^1)^2 + (x^2)^2 - 1\right)^2$$
Then, the differential is
$$dF_{(x,y)} = \begin{bmatrix} 4x^1 \left((x^1)^2 + (x^2)^2 - 1\right) & 4x^2 \left((x^1)^2 + (x^2)^2 - 1\right) \end{bmatrix}$$

THen, all points of $\mathbb{S}^1$ are critical, but $\mathbb{S}^1$ is still an embedded submanifold of $\mathbb{R}^2$. So, the converse of RLST does not necessarily hold.

- Consider the "height function" on a torus $F : \mathbb{T}^2 \xrightarrow{\text{"height func."}} \mathbb{R}^2$

Above, what we did was find the conditions where a level set of a function is a submanifold. Now, given a manifold, how do we *define* a function such that the submanifold forms one of its level sets?

1.2 Defining Functions

Given a submanifold $S^k \subseteq M^m$ of M,

- a smooth map $F : M^m \to N^n$ such that $S = F^{-1}(q)$ for some regular value $q \in N$ is a ***defining function for*** S
- if $p \in S$ and $p \in U \subseteq_{open} M$, then a smooth map $F : U \to N$ is a ***local defining function*** for S at p if $S \cap U = F^{-1}(q)$ for some regular value $q \in N$.

Theorem: Given a subset $S \subseteq M^m$, S is a $k-$dimensional submanifold if and only if there exsit local defining functions $F : U \to \mathbb{R}^{m-k}$ at every point $\in S$.

(Proof follows from k-slicing and constant rank level set theorem)

1.3 Tangent Space to a Submanifold

[Write from image]

In a local k-slice chart for M, $\big(U, \big(x^1, \ldots, x^m\big)\big)$ we have

$$S \cap U = \{x^{+1} = c^{k+1}, \ldots, x^m = c^m\}$$

[Write from image]

If $F : U \subseteq M \to N$ is a local defining function for S, i.e. $U \cap S = F^{-1}(q)$ for a regular value q, then the extrnisic tangent space to S is

$$T_p^{\text{extrnisic}} S = \ker dF_p$$

Example: The group of orthogonal matrices

The orthogonal group is

$$O(n) = \{A \in \mathbb{R}^{n\times n} \ : \ A^T A = \mathrm{Id}_{n\times n}\} \subseteq \mathbb{R}^{n\times n} = \mathbb{R}^{n^2}$$

Defining the map $F : \mathbb{R}^{n\times n} \to \mathbb{R}^{n\times N}_{\text{symm.}}$ $\big(\cong \mathbb{R}^{n(n+1)/2}\big)$ defined as

$$A \mapsto A^T A$$

> *Note:* $\left(A^T A\right)^T = A^T \left(A^T\right)^T = A^T A$

Then, the orthogonal group is just the pre-image of the identity i.e. $O(n) = R^{-1}\left(\mathrm{Id}_{n\times n}\right)$. We want to check that $\mathrm{Id}_{n\times n}$ is a regular value of F.

Let $A \in O(n)$, and compute the differential which maps tangent vectors as

$$\begin{aligned} dF_A : T_A\mathbb{R}^{n\times n} &\to T_{F(A)}\mathbb{R}^{n\times n}_{\text{Symm.}} \\ B &\mapsto \left.\frac{d}{dt}\right|_{t=0} F(A+tB) \end{aligned}$$

Now,

$$\begin{aligned} \left.\frac{d}{dt}\right|_{t=0} F(A+tB) &= \left.\frac{d}{dt}\right|_{t=0} (A+tB)^T(A+tb) \\ &= \left.\frac{d}{dt}\right|_{t=0} A^TA + t\left(B^TA + A^TB\right) + t^2B^TB \\ &= B^TA + A^TB \end{aligned}$$

We need to check that dF_A is surjective, which is equivalent to checking that the kernal satisfies the Rank Nullity Theorem.

$$\begin{aligned} \dim\ker dF_A &= \dim\mathbb{R}^{n\times n} - \dim\mathbb{R}^{n\times n}_{\text{symm.}} \\ &= n^2 - \frac{n(n+1)}{2} \\ &= \frac{n(n-1)}{2} \end{aligned}$$

Notice that this is exactly the dimension of the space of $n\times n$ anti-symmetric matrices which maes sense as

$$\begin{aligned} \ker(dF_A) &= \{B \in \mathbb{R}^{n\times n} \ : \ B^TA = -A^TB\} \\ &= \{B \in \mathbb{R}^{n\times n} \ : \ \left(A^TB\right)^T = -A^TB\} \\ &= \{B \in \mathbb{R}^{n\times n} \ : \ B = AC, \text{ for some antsymmetric } C\} \end{aligned}$$

[Fill in from images]

Also, a very often used tangent space is

$$T_{\mathrm{Id}_{n\times n}}$$

$O(n)$ is a lie group and $\mathbb{R}^{n\times n}_{\text{antisymm.}}$ is its Lie Algebra.
